Hosted MPC Overview

Updated 2 years ago

Notes:

- This feature requires using SGX Co-Signers, hosted in the cloud or on-premises.
- To learn how to host and deploy an SGX Co-Signer see our [SGX API Co-Signer setup](#) article.

The Hosted MPC feature allows you to completely control the MPC key shares by hosting all three Co-Signers in your own environment, either in the cloud or on-premises. This approach ensures compliance with specific business or regulatory requirements set by regional regulators, internal policies, or end-users.

Glossary

- **Primary Co-Signer:** A Mobile Device with the Fireblocks mobile app installed on it, or an API Co-Signer running on an SGX machine that holds one of the three MPC key shares.
- **Guard Co-Signer:** An SGX machine that holds another third of the MPC key shares.

Fireblocks utilizes [MPC-CMP signing](#) via three Co-Signers, each holding a third of the key shares. In the default **SaaS MPC model**, you hold one third of the key shares and Fireblocks holds the other two thirds. The Fireblocks mobile app or the API Co-Signer, which is deployed in your environment, performs the signing.

In the **Hosted MPC** model, you own, host, and deploy all three key shares via three Co-Signers. These three Co-Signers are the API Co-Signer, called a Primary Co-Signer here, and two Guard Co-Signers. They are all necessary to complete the MPC signing process.
